Project Narrative: Everyone shares a board; people remove pixels until someone removes the Last Pixel.

Tools Breakdown and diagrams:

Tools, library, hardware, IDE, target platform or OS, APIs, services

Backend:

- **AWS EC2** instance runs the master program
- Python program with **FastAPI**, possibly **SQLite** libraries
 - **FastAPI** websockets handle multiplayer connection and updates the board live
 - **SQLite** would allow an easy way to keep permanent leaderboard storage in the event that the server shuts down, or the python program crashes/terminates
 - Python **uuid** module may help create a unique session ID
- Server processes click requests, resolving simultaneous pixel clicks between players independently of their machines

Frontend:

- Webpage made with **HTML** (to function) and **CSS** (to look pretty)
- A bit of **JavaScript** may be implemented to allow users to send/receive from the server better

Target platform:

- Website on a browser allows the game to be OS agnostic
